Abstract: This study is a statistical revision of the phytosociological data stored in the Slovak National Vegetation Database (SNVD). The affinity of vascular plants, bryophytes and lichens for higher syntaxa occurring in Slovakia (alliances and classes) was calculated using a statistically defined coefficient of fidelity. Additionally, constant and dominant taxa of these syntaxa were identified. A revised list of syntaxa of Slovakia is supplemented.

Key words: Braun-Blanquet approach, classification, JUICE, phytosociology, plant communities, sharpness, syntaxonomy, TURBOVEG, uniqueness, vegetation survey

Acknowledgements

The authors are grateful to the reviewer for his valuable comments and suggestions on this paper, as well as to many people that helped to create and fill the Slovak National Vegetation Database. The authors were able to base conclusions not only on published and their own unpublished phytosociological relevés, but also on numerous unpublished relevés, willingly provided to the SNVD (Depon at Institute of Botany SAS, <http://ibot.sav.sk/cdf/index.html>) by RNDr. Dana Bernátová, CSc.; RNDr. Radmila Bělohlávková; doc. RNDr. Milan Chytrý, PhD.; RNDr. Daniel Dítě, PhD.; RNDr. Zuzana Dúbravcová, CSc.; RNDr. Eva Fajmonová, CSc.; doc. Mgr. Michal Hájek, PhD.; Mgr. Petra Hájková, PhD.; RNDr. Iva Hodálová, CSc.; RNDr. Judita Kochjarová, CSc.; †doc. RNDr. Štefan Maglocký, CSc.; prof. Dr. Ladislav Mucina, PhD.; RNDr. Libuše Paclová; RNDr. Anton Petrík; Mgr. 1.1 Introduction

Species composition and the spatial structure of vegetation reflect the complexity of biotic and abiotic factors in a habitat, including climatic, relief, edaphic and biotic particularities of the habitats. Due to specific ecological characteristics of the habitats during the course of evolution, groups of species and communities, optimally adapted to these conditions, have been selected (VALACHOVIČ 1990). These plants then thrive and reproduce freely and, based on intra- and interspecific competitive and selective stress, they form more or less extensive populations of one or more plant taxa coexisting in time and space in dynamic balance (cf. MORAVEC 1994a). These plant assemblages are called plant communities, or phytocoenoses, and their study is called phytosociology.

Following genetically defined tolerance to various ecological factors, we distinguish between generalists (species able to thrive in a wide variety of environmental conditions) and specialists (species able to thrive only in a narrow range of environmental conditions). Specifically, it is the species' range of tolerance to a particular ecological factor (or complex of several factors), together with the competitive ability of other species, that defines the range of potential habitats for a species. Ecological gradients are reflected by changes in composition of species of the communities and the ecological amplitudes of a particular community are manifested by transition to another community (HUSOVÁ & MORAVEC 1994). Based on the knowledge of optima of particular taxa in gradients of ecological characteristics, gained from ecological and phytosociological research, we are able to define the fidelity of these taxa to particular syntaxa (or groups of syntaxa) that occupy habitats with specific ecological characteristics. Species specific for a particular plant community, and at the same time distinguishing it from other vegetation units, are called diagnostic (WHITTAKER 1962). These include characteristic species (with limited occurrence in a particular vegetation unit) and differential species (determining the particular vegetation unit against only some other particular units, and overlapping with others). The concept of characteristic species was established by BROCKMANN-JEROSCH (1907) at the beginning of 20th century. As characteristic, he defined taxa occurring only in particular vegetation unit. Diagnostic taxa are often correlated with particular eco-

logical and geographical characteristics of plant communities. In addition, the vegetation units are usually characterised by a group of coenologically correlated diagnostic taxa, which means that they repeatedly co-occur in nature. The larger the group of diagnostic taxa, the better and more accurate is the characterisation of the particular unit (MORAVEC 1994b). In most cases, the groups of diagnostic taxa have mainly regional validity and the same species can occur in different species combinations in different regions (e.g., in other mountain ranges with different florogenesis). This fact has led to replacement of the traditionally used, and strictly defined, concept of characteristic species for more liberal terms like diagnostic species—including characteristic and differential species, or characteristic species combinations—including characteristic species, differential species and species with higher constancy (CHYTRÝ & TICHÝ 2003).

From the beginning, the concept of diagnostic taxa has been always linked to the concept of fidelity – the occurrence or abundance of species in a particular vegetation unit. The first approaches to assess fidelity values were rather intuitive (SZAFAŘ & PAWŁOWSKI 1927). These were later replaced, as the development of more powerful computers and software for vegetation data analysis progressed, by more objective statistical analyses and methods (cf. GOODALL 1953; JUHÁSZ-NAGY 1964; VAN DER MAAREL et al. 1978; BRUEL-HEIDE 1995, 2000; DUFRÈNE & LEGENDRE 1997; BOTTA-DUKÁT & BORHIDI 1999; CHYTRÝ et al. 2002, 2006; CHYTRÝ & TICHÝ 2003).

To make the knowledge of ecological and coenological affinity of particular species exploitable for other scientific disciplines and sufficiently organized, a compendious survey of vegetation units was prepared, serving as an irreplaceable tool for the generation of a conceptual basis for phytosociology (CHYTRÝ 2000). From the inception of phytosociology, many different hierarchical systems have been created, continuously developing owing to increasing number of phytosociological relevés and improving knowledge on vegetation of larger geographical areas or mountain ranges. Generally, as the main criterion of ordering the vegetation units in surveys was accepted the floristic composition of plant communities, reflecting more or less the different ecology and physiognomy of the stands, signified their different ecology.

Vegetation studies arising out of the data collected in the high mountains became the basis of phytosociology (see RÜBEL 1911; BRAUN-BLANQUET & JENNY 1926 etc.). Hence, it is not surprising that the first phytosociological surveys of plant communities (from the Slovak and Polish territories) and the lists of species linked to particular vegetation units were published from the Tatra Mts, the highest mountains of the Carpathian mountain range (cf. SZAFAŘ et al. 1923, 1927; PAWŁOWSKI & STECKI 1927; PAWŁOWSKI et al. 1928; PAWŁOWSKI 1925, 1935).

Local studies were progressively altered by vegetation surveys of larger regions. The first comprehensive vegetation surveys in former Czechoslovakia were published by KLIKA & NOVÁK (1941), KLIKA & HADAČ (1944) and KLIKA (1948, 1955). In addition to the hierarchical system of vegetation units, the authors specified diagnostic taxa of classes, orders and alliances. They did not distinguish characteristic and differential taxa. A few years later, groups of indicator species for individual alliances and suballiances were defined by HOLUB et al. (1967) in their survey of higher vegetation units of the former Czechoslovakia. These groups included characteristic and differential species, as well as species with higher constancy. According to CHYTRÝ & TICHÝ (2003), all mentioned lists of syntaxa and their diagnostic species [or groups of indicator (diagnostic) species] have

been characterised with a high degree of subjectivity in selection of diagnostic species and an inability to differentiate between true diagnostic species and species with higher frequency but low diagnostic value. As a result, it is difficult to distinguish well and poorly delimited vegetation units.

The necessity of a detailed and comprehensive survey of plant communities in Slovakia led to the founding of a “Vegetation of Slovakia” edition in the 1990s. Within this edition, a series of comprehensive monographs “Plant communities of Slovakia” was published, dealing with pioneer (VALACHOVIČ et al. 1995), synanthropic (JAROLÍMEK et al. 1997), wetland (VALACHOVIČ et al. 2001) and high mountain vegetation (KLIMENT et al. 2007). In the near future, the survey of meadow and pasture vegetation will be published, and the series will be finished by a survey of forest and shrub vegetation (VALACHOVIČ 2006). This “Slovak survey initiative” has origin at the Department of Geobotany of the Institute of Botany, Slovak Academy of Sciences, coordinated there in parallel with publishing of vegetation surveys in other parts of Europe (GRABHERR & MUCINA 1993; MUCINA et al. 1993a,b; OBERDORFER 1977, 1978, 1983, 1992; RODWELL 1991a,b, 1992, 1995; SCHAMINÉE et al. 1995a, b, 1996, 1998; DIERSCHKE 1996 et seq.; STORTELDER et al. 1999; BERG et al. 2004). Recently, alongside the vegetation surveys of Slovakia, the preparation of an expert system for identification of individual vegetation units in Slovakia has started, based on the methodology of Czech colleagues (cf. CHYTRÝ 2007), using an external a priori defined criteria created by, for example, the Cocktail method (BRUELHEIDE 1995, 2000). The first result is the survey of meadow and pasture vegetation (JANIŠOVÁ et al. 2007).

A publication from our colleagues from the Masaryk University in Brno (CHYTRÝ & TICHÝ 2003) about diagnostic species of alliances and classes of the Czech Republic was the main inspiration for this book. Hence, we decided to analyse phytosociological relevés, stored in the Slovak National Vegetation Database – SNVD (VALACHOVIČ 1996, 1999; HEGEDÜŠOVÁ 2007, ŠIBÍKOVÁ et al. 2009), in the database program TURBOVEG (HENNEKENS 1995, HENNEKENS & SCHAMINÉE 2001) using the same methodology and then to present the results of statistical analyses of phytosociological data from Slovakia to the general public.

The aims of this paper are **a)** to evaluate the affinity of individual taxa occurring in Slovakia to particular vegetation units (alliances and classes) using statistically defined fidelity values (CHYTRÝ et al. 2002); **b)** to evaluate the quality of delimitation of individual higher syntaxa (alliances and classes) included in the syntaxonomical scheme presented in this book (and recently used in SNVD) and at the same time to point out its strong as well as weak spots.

1.2 Material and Methods

1.2.1 Data set

The survey is based on the analysis of 49,459 phytosociological relevés (30,706 published and 18,753 unpublished) of plant communities from Slovakia and from border zones of Poland, Hungary and the Czech Republic. The data was obtained in June 2007 from the SNVD (HEGEDÜŠOVÁ 2007, ŠIBÍKOVÁ et al. 2009, www.ibot.sav.sk/cdf), and

from private databases of the authors. All relevés were sampled following the standard procedures of the Zürich-Montpellier School (BRAUN-BLANQUET 1964, WESTHOFF & VAN DEN MAAREL 1978), frequently using the modified 9-degree Braun-Blanquet's sampling scale (BARKMAN et al. 1964) and stored in a TURBOVEG database (HENNEKENS & SCHAMINÉE 2001). The data was exported into JUICE 6.4.6 software (TICHÝ 2002) for analysis.

Only the relevés assigned to syntaxon at least at the alliance level were included in the analysis. Syntaxa names of relevés in the database followed the original papers, except syntaxa that were recently syntaxonomically and nomenclaturally revised [e.g., some communities occurring at high altitudes (cf. KLIMENT et al. 2007)]; these syntaxa reflect the current syntaxonomical system presented in Appendix 1 and Chapter 2. Relevés without a locality were deleted.

In the next step, we eliminated relevés taken in plots of extreme size [relevés < 50 m² or > 1,000 m² for forests, < 10 m² or > 200 m² for shrub vegetation, and < 2 m² or > 100 m² for herbaceous vegetation (except *Salicetea herbaceae* and *Sedo-Scleranthesetea*, where the size criterion of individual relevés was 1 to 100 m²)]. A final data set of 43,414 phytosociological relevés was prepared for data analysis.

Since the heterogeneous origin of the data in large phytosociological databases may seriously influence the results of their analysis, KNOLLOVÁ et al. (2005) propose some strategies for stratified re-sampling of such databases, which may improve the representativeness of the data. In spite of frequent use of geographical stratification in similar recent studies (cf. CHYTRÝ & TICHÝ 2003, CHYTRÝ et al. 2007), we decided to analyse our data without any stratification. The main reason was that we considered the bias induced by the elimination of a large amount of data, especially from rare communities with naturally small area of distribution (e.g., communities of the classes *Erico-Pinetea*, *Carici rupestris-Kobresietea*, *Salicetea herbaceae* or the alliance *Hackelion deflexae*), and of data with inexactly defined geographical coordinates, as more serious than bias caused by oversampling of some localities. We came to this decision, to a certain extent, because it was not possible to generate the exact geographical coordinates of most of the older relevés until now. This situation has changed only recently with the use of high-quality maps and aerial photographs and various geographical software such as ArcGIS (ESRI 2005) or Google Earth (<http://earth.google.com/>), which facilitate the exact localisation of individual older phytosociological relevés.

Taxa determined only to the genus level were excluded. The overwhelming majority of species determined to subspecies level were fused to the species level; only in a few cases (different environmental requirements, e.g., altitudinal) were the lower taxonomical units accepted. Some taxa were included into more broadly-defined aggregates:

- Achillea millefolium* agg. – including *A. asplenifolia*, *A. collina*, *A. millefolium*, *A. pannnonica*, *A. setacea*;
- Alchemilla* spec. div. – all *Alchemilla* species;
- Amaranthus hybridus* agg. – *A. bouchonii*, *A. cruentus*, *A. powelii*, *A. retroflexus*;
- Anthoxanthum odoratum* agg. – *A. alpinum*, *A. odoratum*;
- Arabis hirsuta* agg. – *A. hornungiana*, *A. nemorensis*, *A. sagittata*, *A. sudetica*;
- Arabidopsis arenosa* agg. – *A. arenosa*, *A. carpatica*, *A. petrogena*;
- Arenaria serpyllifolia* agg. – *A. leptoclados*, *A. serpyllifolia*;

Aster novi-belgii agg. – *A. laevis*, *A. lanceolatus*, *A. novi-belgii*;
Campanula rotundifolia agg. – *C. mentiens*, *C. rotundifolia*, *C. tatrae*;
Cardamine pratensis agg. – *C. dentata*, *C. matthioli*, *C. pratensis*;
Carex atrata agg. – *C. aterrima*, *C. atrata*;
Carex buxbaumii agg. – *C. buxbaumii*, *C. hartmanii*;
Carex flava agg. – *C. flava*, *C. lepidocarpa*, *C. demissa*, *C. viridula*;
Carex muricata agg. – *C. chabertii*, *C. divulsa*, *C. muricata*, *C. contigua*;
Carex praecox agg. – *C. curvata*, *C. praecox*;
Carex vulpina agg. – *C. otrubae*, *C. vulpina*;
Carlina vulgaris agg. – *C. biebersteinii*, *C. vulgaris*;
Centaurea jacea agg. – *C. jacea*, *C. macroptilon*, *C. × fleischeri*;
Centaurea phrygia agg. – *C. nigra*, *C. phrygia*, *C. pseudophrygia*, *C. stenolepis*;
Cerastium brachypetalum agg. – *C. brachypetalum*, *C. tenoreanum*;
Cerastium fontanum agg. – *C. fontanum*, *C. holosteoides*, *C. lucorum*;
Cerastium pumilum agg. – *C. glutinosum*, *C. pumilum*, *C. semidecandrum*;
Chenopodium album agg. – *C. album*, *C. opulifolium*, *C. strictum*, *C. sueicum*;
Cladonia gracilis agg. – *C. gracilis*, *C. macroceras*;
Cladonia pyxidata agg. – *C. chlorophphaea* (Flörke ex Sommerf.) Spreng., *C. grayi* G.K. Merrill ex Sandst., *C. merochlorophphaea* Asahina, *C. pocillum* (Ach.) O. J. Rich.;
Colymbada scabiosa agg. – *C. scabiosa*, *C. badensis*;
Cornus sanguinea agg. – *C. australis*, *C. hungarica*, *C. sanguinea*;
Crocus discolor agg. – *C. discolor*, *C. heuffelianus*;
Dactylorhiza incarnata agg. – *D. incarnata*, *D. ochroleuca*;
Dactylorhiza maculata agg. – *D. fuchsii*, *D. maculata*;
Dryopteris carthusiana agg. – *D. carthusiana*, *D. dilatata*, *D. expansa*;
Dryopteris filix-mas agg. – *D. affinis*, *D. filix-mas*;
Eleocharis palustris agg. – *E. mamillata*, *E. palustris*, *E. uniglumis*;
Epilobium tetragonum agg. – *E. lamyi*, *E. tetragonum*;
Erigeron acris agg. – *E. acris*, *E. angulosus*;
Erophila verna agg. – *E. spathulata*, *E. verna*;
Euphrasia stricta agg. – *E. pectinata*, *E. slovaca*, *E. stricta*;
Festuca rubra agg. – *F. heteromalla*, *F. nigrescens*, *F. rubra*;
Festuca valesiaca agg. – *F. pseudodalmatica*, *F. valesiaca*;
Galeobdolon luteum agg. – *G. luteum*, *G. montanum*;
Galium mollugo agg. – *G. album*, *G. mollugo*, *G. pycnotrichum*;
Galium palustre agg. – *G. elongatum*, *G. palustre*;
Galium pumilum agg. – *G. anisophyllum*, *G. austriacum*, *G. pumilum*, *G. saxatile*;
Galium verum agg. – *G. verum*, *G. wirtgenii*;
Glechoma hederacea agg. – *G. hederacea*, *G. hirsuta*;
Gymnadenia conopsea agg. – *G. conopsea*, *G. densiflora*;
Hypnum cupressiforme agg. – *H. cupressiforme*, *H. lacunosum* (Brid.) Hoffm. ex Brid.;
Juncus bufonius agg. – *J. bufonius*, *J. minutulus*, *J. ranarius*;
Juniperus communis agg. – *J. communis*, *J. sibirica*;
Kiaeria starkei agg. – *K. falcata*, *K. starkei*;
Leucanthemum vulgare agg. – *L. gaudinii*, *L. ircutianum*, *L. margaritae*, *L. vulgare*;
Luzula campestris agg. – *L. campestris*, *L. divulgata*, *L. multiflora*, *L. pallescens*;

Malus sylvestris agg. – *M. domestica*, *M. sylvestris*;
Molinia caerulea agg. – *M. arundinacea*, *M. caerulea*;
Montia fontana agg. – *M. fontana*, *M. hallii*;
Myosotis scorpioides agg. – *M. brevisetacea*, *M. caespitosa*, *M. nemorosa*, *M. scorpioides*;
Myosotis sylvatica agg. – *M. stenophylla*, *M. sylvatica*;
Odontites vulgaris agg. – *O. verna*, *O. vulgaris*;
Oenothera biennis agg. – *O. biennis*, *O. hoelscheri*, *O. depressa*, *O. suaveolens*;
Ornithogalum umbellatum agg. – *O. kochii*, *O. umbellatum*;
Phleum pratense agg. – *P. bertolonii*, *P. pratense*;
Plagiognathus affine agg. – *P. affine*, *P. elatum*, *P. ellipticum*, *P. medium*, *P. rostratum*;
Poa annua agg. – *P. annua*, *P. supina*;
Poa pratensis agg. – *P. angustifolia*, *P. humilis*, *P. pratensis*;
Polygonum aviculare agg. – *P. arenastrum* (prevails), *P. aviculare*, *P. rurivagum*;
Polytrichum formosum agg. – *P. formosum*, *P. longisetum*, *P. pallidisetum*;
Potamogeton pusillus agg. – *Potamogeton berchtoldii*, *Potamogeton pusillus*;
Potentilla argentea agg. – *P. argentea* (prevails), *P. neglecta*;
Pseudolysimachion spicatum agg. – *P. incanum*, *P. orchideum*, *P. spicatum*;
Puccinellia distans agg. – *P. distans*, *P. limosa*;
Pulmonaria officinalis agg. – *P. officinalis*, *P. obscura*;
Pulsatilla pratensis agg. – *P. pratensis*, *P. zimmermannii*;
Pyrus communis agg. – *P. communis*, *P. pyraster*;
Quercus petraea agg. – *Q. dalechampii*, *Q. petraea*, *Q. polycarpa*;
Quercus pubescens agg. – *Q. pubescens*, *Q. virgiliiana*;
Quercus robur agg. – *Q. pedunculiflora*, *Q. robur*;
Ranunculus auricomus agg. – *R. auricomus*, *R. cassubicus*, *R. transtibiscensis*;
Rhizomnium punctatum agg. – *R. magnifolium*, *R. pseudopunctatum*, *R. punctatum*;
Rosa canina agg. – *R. canina* (prevails), *R. dumalis*, *R. inodora*;
Rubus fruticosus agg. – all species of genus *Rubus* except *R. caesius*, *R. hirtus*, *R. idaeus*,
R. saxatilis;
Salix retusa agg. – *S. kitaibeliana*, *S. retusa*;
Salix rosmarinifolia agg. – *S. repens*, *S. rosmarinifolia*;
Schistidium apocarpum agg. – *S. agassizii*, *S. apocarpum*, *S. atrofuscum*, *S. boreale*,
S. brunnescens, *S. rivulare*, *S. trichodon*;
Scilla bifolia agg. – all native *Scilla* species;
Scleranthus annuus agg. – *S. annuus*, *S. polycarpos*;
Senecio nemorensis agg. – *S. germanicus*, *S. hercynicus*, *S. ovatus*, *S. ucranicus*;
Silene otites agg. – *S. donetzica*, *S. otites*;
Sorbus aria agg. – *S. aria*, *S. austriaca*, *S. graeca*, *S. hazelinszkyana*, *S. pekarovae*,
S. margittaiana, *S. montisalpae*, *S. zuzanae*;
Sphagnum capillifolium agg. – *S. capillifolium*, *S. rubellum*;
Sphagnum palustre agg. – *S. centrale*, *S. palustre*;

Veronica hederifolia agg. – *V. hederifolia*, *V. sublobata*, *V. triloba*;
Viola tricolor agg. – *V. saxatilis*, *V. tricolor*.

It is important to consider that broadly conceived taxa may include variously defined “narrow” taxa, which may affect the interpretation of results. Therefore, we specified the concept of some particular “narrow” taxa in footnotes in Appendices 2 and 3.

Since the span of height of particular vegetation layers was defined differently by early authors, and especially since dwarf specimens of many woody taxa were often noted in different ways, the tree-, shrub- and herb-layer records (including seedlings and juveniles) for every taxon were merged. Finally, every species was present only once in the data set.

In spite of the fact that bryophytes, lichens and macroalgae were not recorded in all relevés, they were retained in the data set because of their proportional occurrence in individual vegetation units. It is important to consider this fact while interpreting the results and to consider the values of diagnostic, constant and dominant cryptogams as overestimated to a certain extent in some syntaxa.

In the next step, all crop plants were eliminated from the dataset. They occurred in some relevés of weed vegetation and they had, in contrast to other naturally occurring weed species, no information value.

Similarly, all species recorded in a single relevé were excluded from the analysis in order to eliminate the random effect on the results. The final number of taxa occurring in the data set was 2,858.

The nomenclature of the vascular plants generally follows the Chromosome number survey of the ferns and flowering plants of Slovakia (MARHOLD et al. 2007) and the Identification key of ferns and flowering plants of the Slovak Republic (MARHOLD et al. 2009). Several exceptions with the author’s citation were used, especially in cases of common and, until now, frequently used names. The subspecies in Appendices 2 and 3 (given without the species name) are marked with asterisks (*). The nomenclature of the bryophytes follows KUBINSKÁ & JANOVICOVÁ (1998) and Check list of Norwegian mosses (ANONYMOUS 2005); the names of lichens are in accordance with BIELCZYK et al. (2003). In both cases, the exceptions are presented with the author’s citation.

The nomenclature of syntaxa follows Chapter 2, which represents the new list of vegetation units of Slovakia, used in SNVD. The former list was published more than 20 years ago by MUCINA & MAGLOCKÝ (1985), and its update was necessary. This list of syntaxa reflects not only the numerous syntaxonomical revisions, based on numerical processing of a large amount of newly obtained phytosociological relevés, but also numerous nomenclatural revisions of syntaxa names in accordance with the International Code of Phytosociological Nomenclature – 3rd edition (WEBER et al. 2000). The list had to be finished before the beginning of the data analysis itself and, therefore, it does not follow the latest syntaxonomical concepts in some vegetation units. Thus, in relevant places we refer to publications with the current concept of phytosociological systems of particular vegetation types (e.g., JANIŠOVÁ et al. 2007, DÍTĚ et al. 2007).

Since the syntaxon codes in SNVD (VALACHOVIČ 1996, 1999) markedly changed from the 1990s, Appendix 1 was compiled as a synopsis of analyzed alliances and classes. The

units are arranged by Turboveg Code (TV code) for an easy determination of individual syntaxa in Appendices 2 and 3.

1.2.2 Data analysis

Relevés with deviating floristic composition from individual classes were determined by DCA analysis in the CANOCO program (TER BRAAK & ŠMILAUER 2002) and afterwards excluded from the data set or if fitting, thus included into the most similar class.

The final data set of 43,222 phytosociological relevés was analysed in the program JUICE, version 6.4.6 (TICHÝ 2002). Within diagnostic group of taxa we distinguished diagnostic, constant and dominant taxa. Diagnostic species were statistically determined on the basis of fidelity concept (BRUELHEIDE 1995; CHYTRÝ et al. 2002, 2006; CHYTRÝ & TICHÝ 2003; CHYTRÝ 2007). Fidelity offers more stringent rules for including species to the group of diagnostic species.

Diagnostic taxa for each group (alliances and classes) are determined using the phi coefficient (SOKAL & ROHLF 1995, CHYTRÝ et al. 2002). Each taxon is characterised by fidelity (Φ , Phi-coefficient), which represents the rate of statistical association between the occurrence of species and the relevés assigned to the vegetation unit. It ranges from -1 to 1 (in the output the Phi-coefficient is multiplied by 100). The fidelity expresses a diagnostic value of species for given vegetation unit (CHYTRÝ 2007). Species with high fidelity can be regarded as diagnostic (characteristic or differential). The highest Phi value is yielded if the taxon occurs in all relevés of the given vegetation unit and is absent elsewhere. A positive value lower than 1 means that the species is absent in some relevés of the given vegetation unit or present in some relevés outside the vegetation unit. A zero value is yielded when the species percentage frequency in the vegetation unit equals the percentage frequency in the rest of the data set (CHYTRÝ & TICHÝ 2003). The phi-coefficient was standardized to the equal relevé size of all groups; target group being of the same size as the others (CHYTRÝ et al. 2006, TICHÝ & CHYTRÝ 2006). The size of groups was virtually equalised to 1/47 of the total number of all relevés in the data set for classes, and to 1/175 for alliances. The using of this method is partially influenced by the fact, that smaller groups (units with smaller number of relevés) are more homogeneous than larger ones and hence have more diagnostic species with high fidelity. Thus, those smaller units seem to be overestimated, what should be considered while interpreting the results. To reduce this effect, the species with the probability of random occurrence in the vegetation type lower than 0.001 ($P < 0.001$) yielded by Fisher's exact test (CHYTRÝ et al. 2002, 2006; CHYTRÝ 2007) were excluded from the list of diagnostic taxa. Despite this fact, few units still seem to be more or less overestimated. Conversely, if a method without virtual standardisation of all groups was used for the calculation of fidelity, as did CHYTRÝ & TICHÝ (2003) in their pioneer study which serves as a model for this study, it would have an antagonistic effect. Alliances and classes with small number of relevés would be more or less underestimated and groups of diagnostic taxa might have been affected by the random effect. After comparison and evaluation of several pilot analyses we decided to use the newer method (TICHÝ & CHYTRÝ 2006) with the careful interpretation of diagnostic taxa of vegetation units with small number of relevés (frequently they are naturally rare communities), which can be overrated and hence biased. The species with a fidelity of

above 24 ($\Phi > 0.24$) were considered as diagnostic. This value was selected subjectively, as it proved informative after a preliminary investigation of the obtained results.

Constant taxa are those with a high occurrence frequency in the given vegetation unit. The threshold frequency values for constant species were selected differently for classes (25 %) and alliances (40 %), because the latter are more narrowly conceived and therefore more homogeneous vegetation units.

Dominant taxa were defined as those having a percentage cover higher than 50 % at least in 3 % of relevés in the given vegetation unit. In such a way, species which only rarely or never attain high cover are not included in the output.

Diagnostic, constant and dominant taxa defined in this manner are presented in Appendix 2, ordered following TURBOVEG codes used in the SNVD. The diagnostically important taxa of individual syntaxa are sorted according to their decreasing values of the phi coefficient multiplied by 100 (diagnostic taxa), percentage frequency of occurrence (constant taxa), and percentage frequency of cases with taxon cover exceeding 50 % (dominant taxa). In Chapter 2 the syntaxa are arranged by habitat types: non-forest aquatic, wetland, non-forest terrestrial rock fissures and screes, high-altitude vegetation, grasslands, fringes, shrubs, forests and finally synanthropic vegetation.

Statistically defined diagnostic taxa enabled us to quantify the quality of syntaxa (alliances and classes) delimitation. For this purpose, the criteria of sharpness and uniqueness were used, similarly as in CHYTRÝ & TICHÝ (2003).

Sharpness is given by index S that “is defined as the number or quality of diagnostic species in a vegetation unit, relative to the average species richness of its stands. A vegetation unit is sharp if a large proportion of its species are confined to it, being mostly absent or rare in other vegetation units, while it is progressively less sharp if most of its species are generalists frequently found also in other vegetation units. The Sharpness Index (S) ranges in the interval $(0; \infty)$ and attains high values for sharp vegetation units and low values for unsharp vegetation units. The highest values of the Sharpness Index are attained if a vegetation unit possesses many diagnostic species with a high diagnostic capacity (e.g., with a high Phi value). Lower, but still rather high values can be yielded either in case of few diagnostic species with a high diagnostic capacity or in case of many diagnostic species with a relatively poor diagnostic capacity” (CHYTRÝ & TICHÝ 2003).

Uniqueness was used for the first time in the paper of CHYTRÝ & TICHÝ (2003) to identify unique vegetation units in the data set. It “expresses whether or not there are similar vegetation units of the same rank (e.g., class or alliance). A vegetation unit is unique if none of its diagnostic species has simultaneously diagnostic status in other vegetation units, while its uniqueness decreases if it shares its diagnostic species with other vegetation units.” Uniqueness Index is low for those vegetation units whose diagnostic species are mostly shared with other vegetation units (TICHÝ & HOLT 2006). Uniqueness is calculated in two steps. First, an Asymmetric Similarity Index (T) between every pair of relevant vegetation units is computed. Thereafter, the actual Uniqueness Index for each vegetation unit is calculated using the previously obtained index T (CHYTRÝ & TICHÝ 2003, TICHÝ & HOLT 2006).

1.3 Results and Discussion

The linkage of taxa occurring in Slovakia to particular alliances and classes presented in this handbook (Appendix 1 and Chapter 2) was calculated based on predetermined criteria. Final lists of diagnostic, constant and dominant taxa are summarised in Appendices 2 and 3. In Appendix 2 the groups of taxa are assigned to the relevant syntaxa (alliances and classes), which are ordered following the TURBOVEG code of classes and alliances. In Appendix 3, all taxa are ordered alphabetically. For a correct interpretation of results, it is important to remember that small groups (vegetation units with a small number of relevés) are more homogeneous than larger ones and they have more diagnostic taxa with higher fidelity. These units might be more or less overestimated because of standardising an analysed dataset to an equal relevé size of all groups (see above). As the SNVD has had no professional manager and has been managed by volunteers since its establishment, some bias of results might have been caused by subjective mistakes in the database due to computerization of many relevés by non-botanists.

In spite of the fact that classification is not the main research purpose of phytosociology, it has a significant role as a unique tool to organize the accumulated knowledge into a plain system and to form the conceptual apparatus (CHYTRÝ 2000). The last comprehensive list of syntaxa occurring in Slovakia was elaborated by MUCINA & MAGLOCKÝ (1985). Since that time, a huge number of new relevés, including rare or formerly unknown plant communities, have been put into SNVD (HEGEDÜŠOVÁ 2007, ŠIBÍKOVÁ et al. 2009). In addition, a significant advance in the development and use of various database programs and numerical methods has come. Modern computer configurations allow us to analyze up to several thousands of phytosociological relevés. Hence, we realized the presentation of a new list of syntaxa occurring in Slovakia (or, actually, in the Western Carpathians) based on the extensive syntaxonomical and nomenclatural revisions published recently. Instead of creating new classifications, the aim of this list was a critical revision of contemporary phytosociological systems and, in particular, an effort to consider the other European classifications and apply consistent criteria for the whole list of syntaxa.

The idea of a complex evaluation of vegetation, based not only on floristic composition, but also on the qualitative and quantitative participation of all components, together with the spatial distribution and mutual relations, was already applied by REJMÁNEK (1977). Based on this principle, shrub vegetation (class *Rhamno-Prunetea* Rivas Goday et Borja-Carbonell 1961) was separated from broad-leaved deciduous forests; dwarf shrubs (class *Loiseleurio-Vaccinietea* Eggler ex Schubert 1960) were separated from (sub)alpine grasslands (*Caricetea curvulae* Br.-Bl. 1948, syn. *Juncetea trifidi* Hadač 1946) or coniferous forests (*Vaccinio-Piceetea* Br.-Bl. in Br.-Bl. et al. 1939); deciduous shrubs of the *Betulo carpatica-Alnetea viridis* Rejmánek in Huml et al. 1979 were separated from tall-herb communities of the *Mulgedio-Aconitetea* (cf. EGGLER 1952, SCHUBERT 1960, RIVAS GODAY & BORJA-CARBONELL 1961, HUML et al. 1979, WIRTH 1993, PIGNATTI et al. 1995, etc.). Examples mentioned above show that, in many cases, these are communities of a mosaic or ecotone character, similar to the fringe communities of the *Trifolio-Geranietea* Th. Müller 1962 (cf. MUCINA & KOLBEK 1993), originally ordered to the xerothermophilous communities of the class *Festuco-Brometea* Br.-Bl. et Tx. in Br.-Bl. 1949, or on the other hand, to the contact forest communities (mostly *Querco-Fagetea* Br.-Bl. et Vlieger in Vlieger 1937). An acceptation of some classes with ecotonal or mosaic character, such

as *Loiseleurio-Vaccinietea*, *Rhamno-Prunetea* and *Trifolio-Geranietea* on one hand, and the rejection of classes such as *Betulo-Alnetea viridis* and *Roso pendulinae-Pinetea mugo* on the other hand, (cf. GRABHERR & MUCINA 1993, MUCINA 1997) point out the different attitude of the authors towards individual higher syntaxa and makes such phytosociological systems less consistent. In all mentioned and similar cases, we tried to apply equal criteria to obtain a more consistent system.

For including the plant communities into particular classes, we used basic criteria similar to THEURILLAT et al. (1995) in their classification of plant communities of the Alps: **a)** structural homogeneity of all units in the class (stands of similar physiognomy and ecology) and **b)** floristic similarity. Using a combination of these two criteria, together with physiognomical, ecological and floristic characteristics, we suggest a system of higher vegetation units that, in spite of some doubts, might represent a universal phytosociological system, which is better applicable in practise (e.g., Natura 2000). We know that, in some cases, it is difficult to use unified criteria because there are many transitional situations in nature that do not fit into boxes. In these cases, the acceptation or the placement of particular syntaxa into the phytosociological system is more or less a matter of a common consensus among vegetation scientists. The analysis of data from SNVD has already shown that distinguishing some higher syntaxa included in Appendix 1 is superfluous (e.g., *Pulsatillo-Pinetea*). In these cases, the decision to accept or reject a given syntaxa relies on critical evaluation by the reader. We believe that, after careful revision of all vegetation types of Slovakia by formalised methods (cf. CHYTRÝ 2000), and after building an expert system using external, a priori defined criteria created by, for example, the Cocktail method (BRUELHEIDE 1995, 2000), we will be able to present surveys similar to the Vegetation of the Czech Republic (CHYTRÝ et al. 2007) in the near future. However, we assume that the differences in the fidelity values of individual ecologically important taxa to particular syntaxa will not be significantly different from those presented in this book, based on the present state of SNVD. A similar thing might also be seen in the comparison of works from CHYTRÝ & TICHÝ (2003) and CHYTRÝ et al. (2007). These are rather sequential steps, the first being the analysis of a large data set from a particular database, creating hypotheses and assumptions, and determining the second step, which is building an expert system that contains the exact definitions of individual syntaxa and helps in classification of individual relevés to these syntaxa.

The most frequent taxa stored in SNVD are summarised in Table 1. In general, they represent the most eurytopic and most common taxa (including more broadly conceived taxa), which occur in various types of vegetation.

1.3.1 Evaluation of classes

Table 2 comprises all classes ordered by decreasing value of Sharpness Index (S). In this manner, the classes are ranked by decreasing proportion of quality of diagnostic species relative to the average species richness of vegetation stands (CHYTRÝ & TICHÝ 2003). Classes with the highest Sharpness Index comprise rare communities occurring in extreme habitats, such as species-poor halophytic communities of the *Thero-Suaedetea* and communities on blown sands of the *Festucetea vaginatae*, together with species-poor water pioneer communities of classes *Charetea fragilis*, *Potametea* and *Lemnetea*. The latter two were also identified within the sharpest groups in the analysis of Czech data

Table 1. Fifty most frequent taxa in the analysed dataset (43,222 relevés and 2,858 taxa) selected from the SNVD and the number of their occurrences (n) and frequencies (f).

(CHYTRÝ & TICHÝ 2003), due to the specific ecological conditions of aquatic environments in comparison with terrestrial habitats. The relict communities from the most extreme mountain habitats with an occurrence of many arctic-alpine taxa (class *Carici rupestris-Kobresietea*) and relict pine communities of canyons and limestone cliffs (class *Erico-Pinetea*) reach high values of the Sharpness Index as well.

Conversely, tall-herb and nitrophilous communities of the classes *Mulgedio-Aconitea* and *Galio-Urticetea* are the least sharp, due to the occurrence of numerous taxa with a wide ecological range. The class *Thlaspietea rotundifolii* in Slovakia, similar to the Czech Republic (cf. CHYTRÝ & TICHÝ 2003), seems to be one of the least sharp classes, probably due to its pioneer character. The class *Rhamno-Prunetea*, which belongs to syntaxa that are difficult to define by diagnostic taxa, also has a low Sharpness Index.

Classes *Vaccinio-Piceetea* and *Querco-Fagetea* represent natural and semi-natural vegetation. Whereas in the Czech Republic they belong to the sharpest syntaxa (CHYTRÝ & TICHÝ 2003), in Slovakia they show lower sharpness. This difference might result from the unclear classification of spruce communities from lower altitudes, which grow secondarily in beech habitats and are included in the class *Vaccinio-Piceetea*. The other reason for their lower sharpness might be the different ecological amplitude of herbs and trees and shrubs; whereas herbs accurately reflect soil, microclimatic and other properties

Table 2. Sharpness Index (S) and Uniqueness Index (U) of vegetation classes of Slovakia, ranked by decreasing values of the Sharpness index.

Explanations: **Tv Code** – Turboveg Code; **Abb** – Abbreviation of class name; **n** – No. of relevés; **a** – Average taxa No. rounded to the whole number; **hlU** – Ten (twenty) highest [+ + (+)] and lowest [– – (–)] values of the Index U; **sU** – Sequence of the classes ranked by decreasing values of the Index U.

of habitats, the ecological amplitude of most trees and shrubs is much wider (SILLINGER 1935) and reflects mainly meso- and macroclimatic conditions. In this manner, we can explain the floristic similarity of subalpine nitrophilous tall-herb communities of the *Adestostylon alliariae* and dwarf-pine and spruce vegetation occupying similar habitats with available nutrients and soil moisture (ŠIBÍK 2007).

Values of Uniqueness (U) of classes partially correlate with the values of Sharpness Index, which is different from the results obtained by the analysis of the Czech National Phytosociological Database (CHYTRÝ & TICHÝ 2003). A high value of the U Index shows high uniqueness of a given unit. The unit is considered unique when any of its diagnostic taxa (defined by Phi value > 0.05, see CHYTRÝ & TICHÝ 2003) is not concurrently diagnostic in any other unit. The uniqueness of a unit decreases if it shares some diagnostic taxa with other units. In general, rare vegetation units represented by small number of relevés and/or species-poor syntaxa occupying extreme habitats appear to form a group of the most unique units. The opposite group of units with the lowest values of the U Index includes also the classes occurring mostly in the subalpine belt – *Mulgedio-Aconitetea*, *Loiseleurio-Vaccinietea* and *Roso pendulinae-Pinetea mugo*, in which occur many taxa with positive fidelity to several syntaxa. The low frequency or absence of narrow specific forest-alpine transition zones or treeline-ecotone species (cf. KÖRNER 2003) might be explained by the sharing of numerous diagnostic species with several different syntaxa occurring in the subalpine belt.

The pairs of the most similar classes are presented in Table 3. In most cases, pair forming is based on floristic similarity between structurally different units (e.g., *Mulgedio-Aconitetea* and *Betulo carpatica-Alnetea viridis*, *Loiseleurio-Vaccinietea* and *Caricetea curvulae*, *Elyno-Seslerietea* and *Erico-Pinetea*) or between successively ensuing vege-

Table 3. Classes with highest similarity to the other classes. Couples of classes are ranked by decreasing value of index T, which expresses similarity of the classes in the left column to the classes in the right column. Only 40 pairs with the highest similarity are shown.

tation types (*Thlaspietea rotundifolii* and *Carici rupestris-Kobresietea bellardii*, *Asplenietea trichomanis* and *Elyno-Seslerietea*). Some authors (e.g., WESTHOFF 1967, PIGNATTI et al. 1995) do not reflect the differences in structure of floristically similar vegetation units in the syntaxonomical system of higher units (classes). Therefore, some vegetation surveys strictly follow the floristic criterion for delimitation of higher syntaxa (cf. MUCINA 1997). However, these authors also apply this principle only to a certain extent and only in some cases (ŠIBÍK 2007). For example, PIGNATTI et al. (1995) give several examples in their work of “ecoclimatic classes”, but they preferred the ecological differentiation to vertical (and climatic) limits of some communities. In one case, the authors accept the differences between forest communities, based on different stages of succession and, hence, they accept the class *Rhamno-Prunetea*; in another case, they merged subalpine shrub and spruce vegetation (ŠIBÍK 2007).

Similarly to the Czech Republic (CHYTRÝ & TICHÝ 2003), it was also shown in Slovakia that the most similar are the structurally different communities of aquatic vegetation, *Potametea* (submerged vegetation) and *Lemnetea* (pleustonic vegetation). Communities defined on different plot sizes also appear similar – *Sedo-Scleranthesetea* and *Festuco-Brometea*. CHYTRÝ & OTÝPKOVÁ (2003) point out that in some situations, sampling in either small or large plots may result in assignment of relevés to different phytosociological classes or habitat types. Therefore, defining vegetation and habitat types as scale-dependent concepts is needed. The similarity between *Elyno-Seslerietea* and *Erico-Pinetea* also could be interpreted by a different scale of sample plots. Relevés of *Sedo-Scleranthesetea* and *Elyno-Seslerietea* are usually sampled in smaller plots than their adjacent classes.

In addition, few structurally homogeneous vegetation units show high similarity (e.g., *Koelerio-Corynephoretea* and *Festucetea vaginatae*, *Quercetea robori-petraeae* and *Pulsatillo-Pinetea*). In these cases, we might consider merging them into a single class (cf. CHYTRÝ & TICHÝ 2003). It is also important to take into account the fact that some vegetation units are at the border of their range in Slovakia and they are represented by fragmentary stands that lack some specific floristic elements. In a wider geographical context, it is possible that the differentiation of particular syntaxa would be confirmed.

1.3.2 Evaluation of alliances

The alliances *Cypero-Spergularion salinae*, *Halo-Trichophorion pumili* and *Puccinellion limosae*, belonging to the class *Festuco-Puccinellietea* (including inland salt-marshes), together with the *Littorelion uniflorae* (*Isoeto-Littorelletea*) and the *Radiolion linoidis* (*Isoeto-Nanojuncetea*), represent the sharpest alliances of our dataset, probably due to sharp ecological boundaries of these communities in conjunction with low species richness of individual vegetation types (Table 4). Some alliances from the classes with the highest Sharpness Index (e.g., *Thero-Camphorosmion* – *Thero-Suaedetea*, *Oxytropido-Elynion* – *Carici rupestris-Kobresietea bellardii* and *Charion fragilis* – *Charetea fragilis*) can be included in the sharpest units as well.

The appearance of the alliance *Dicrano-Pinion* (*Vaccinio-Piceetea*), and potentially some other vegetation units, among the sharpest units might be misleading to a certain extent due to a small number of relevés being included in a particular unit, which makes it a homogeneous group. In general, we would have expected a lower value of the Sharpness Index because of the unclear concept of this unit in Slovakia and because of

the high floristic similarity to the communities of the alliance *Pino-Quercion (Quercetea robori-petraeae)*.

Similar to the classes (Table 2), some alliances are also predictably unsharp, which may be due to their general unsharpness either within Slovakia or within the whole distributional range. For example, the *Trifolion medii*, the alliance with the lowest value of the S Index, has also reached very low values of sharpness in the dataset from the Czech Republic (cf. CHYTRÝ & TICHÝ 2003). The low values of the Sharpness Index in some alliances of grassland vegetation [*Deschampsion cespitosae*, *Polygono-Triisetion* and *Potentillion anserinae (Molinio-Arrhenatheretea)*] may be a result of unclear syntaxonomical conception and delimitation in the past. After recent processing and revision of grassland vegetation by formalised methods (cf. JANIŠOVÁ et al. 2007), these units may not appear as some of the least sharp vegetations.

Location of the alliance *Alnion incane* (alluvial woodlands) within a group of the least sharp communities is a distinctly different result in comparison with the Czech Republic (CHYTRÝ & TICHÝ 2003), where it is located among the twenty sharpest alliances. We explain this difference by the heterogeneity of the alliance, which comprises two suballiances, *Alnenion glutinoso-incanae* and *Ulmenion*. CHYTRÝ & TICHÝ (2003) assume that in a case like this, the heterogeneous alliance, including two or more well-defined vegetation types, should be characterized by its own groups of diagnostic species. If taken as a single group, these species will have low values of fidelity compared to the alliance, and the Sharpness Index for the alliance will be rather low.

Similar to the class analysis, uniqueness of the alliances was also partially correlated with values of sharpness (Table 4). This is again a difference between our results and those of CHYTRÝ & TICHÝ (2003), where the values of the Uniqueness Index were not correlated with sharpness. In general, the syntaxa with the highest values of sharpness were, in our analysis, the same as the syntaxa with the highest values of uniqueness.

In Table 5, there are pairs of alliances ranked by decreasing values of index T, which expresses similarity of the alliances in the left column to the alliances in the right column. Similar to the analysis of individual classes, high similarities are indicated between the structurally different but floristically similar vegetation types, or between types dependent on a different scale of sample plots (e.g., *Astero alpini-Seslerion calcariae* and *Pulsatillo slavicae-Pinion*, *Juncion trifidi* and *Loiseleurio-Vaccinion*, *Calamagrostion arundinaceae* and *Salicion silesiaca*, *Calamagrostion variae* and *Pulsatillo slavicae-Pinion*).

In addition, alliances forming pairs with successively close vegetation units appear to be the most similar (e.g., *Astero alpini-Seslerion calcariae* and *Potentillion caulescens*). Pairs of the most similar alliances, ranked within particular classes, support their classification within the same class (e.g., *Vaccinion myrtilli* and *Loiseleurio-Vaccinion*, *Festucion versicoloris* and *Oxytropido-Elynnion*, *Sphagnion medii* and *Oxycocco-Empetron hermaphroditii*).

The last group of syntaxa, forming pairs based on sharing diagnostic taxa, were the structurally homogeneous vegetation units (e.g., *Alopecurion pratensis* and *Cnidion venosii*, *Genisto germanicae-Quercion* and *Quercion petraeae*, *Athyrio alpestris-Piceion* and *Chrysanthemo rotundifolii-Piceion*, *Piceion excelsae* and *Abietion albae*). In certain circumstances (e.g., in case of identical ecological characteristics together with the same distributional area), merging these into one unit should be considered. In the case of lowland alluvial meadows (*Deschampsion cespitosae*, *Alopecurion pratensis*, *Cnidion*

Table 4. Sharpness Index (S) and Uniqueness Index (U) of vegetation alliances of Slovakia, ranked by decreasing values of the Sharpness index.

Explanations: **Tv Code** – Turboveg Code; **Abb** – Abbreviation of alliance name; **n** – No. of relevés; **a** – Average taxa No. rounded to the whole number; **hlU** – Twenty (Fourty) highest [++ (+)] and lowest [-- (-)] values of the Index U; **sU** – Sequence of the classes ranked by decreasing values of the Index U.

venosi, *Veronica longifoliae-Lysimachion vulgaris*), their similarity was recently reflected in the current phytosociological system (cf. BOTTA-DUKÁT et al. 2005, ČERNÝ & ŠUMBEROVÁ 2007, HÁJKOVÁ 2007). The high similarity of several syntaxa to another syntaxa may result from their unsharpness (cf. CHYTRÝ & TICHÝ 2003).

Table 5. Alliances with highest similarity to the other alliances. Couples of alliances are ranked by decreasing value of index T, which expresses similarity of the alliances in the left column to the alliances in the right column. Only 100 pairs with the highest similarity are shown.

1.4 Conclusions

This study represents the statistical revision of phytosociological data stored in the SNVD. The affinities of vascular plants, bryophytes and lichens occurring in Slovakia to the major syntaxa (alliances and classes) are calculated using a statistically defined coefficient of fidelity. Additionally, constant and dominant taxa of particular syntaxa were identified.

The evaluation of vegetation units by sharpness and uniqueness criteria allows us to identify reliable delimited alliances and classes (within the phytosociological system presented in Appendix 1 and Chapter 2) or to point out those for which delimitation is problematic and which are more difficult to define by statistical principles. The syntaxonomical revision and the delimitation of some units with low values of sharpness and uniqueness should be considered.

There are several problems that may bias the results of large data set analysis of phytosociological relevés, such as the preference for data gathering in certain vegetation types or in certain regions, the low number of relevés from certain vegetation units (e.g., from naturally rare plant communities), and multiple taxonomic concepts. In spite of these difficulties, looking at the quality and the distribution of our data in SNVD, as well as at the consistency of the phytosociological system presented, we consider the current results to be more than useful. Using expert knowledge, we were able to explain the inconsistencies in the results and point them out in the particular chapter (e.g., the certain overestimation of vegetation units with lower number of relevés included, which represent more homogeneous groups). Of course, there are several alliances or classes where the results could be biased due to their fragmentary development or erroneous delimitation in Slovakia.

The presented results are important not only for scientists (such as botanists, zoologists, and ecologists), but also for nature conservation institutions, since this data is an important and essential source of much floristic information on the occurrence of vascular and non-vascular plants in relevant plant communities with specific environmental characteristics.

1.5 Zhrnutie (Slovak Summary)

Charakter vegetácie je daný komplexom biotických a abiotických činiteľov podmieneňných špecifíkami klímy, reliéfu, edafických a biotických pomerov na stanovišti. Rozsah tolerancie druhu k určitému ekologickému faktoru (alebo komplexu viacerých faktorov) v spojení s konkurenčnou schopnosťou iných druhov určuje, na akých rôznych stanovištiach sa môže konkrétny taxón vyskytovať. Ekologické gradienty sa prejavujú zmenami druhového zloženia spoločenstiev a hranice ekologických amplitúd určitého spoločenstva ako prechod k inému spoločenstvu (HUSOVÁ & MORAVEC 1994). Na základe poznania optimálnych jednotlivých taxónov v gradientoch ekologických faktorov, získaného ekologickým a fytocenologickým výskumom, môžeme stanoviť vernosť jednotlivých taxónov k určitým syntaxám (resp. skupinám spoločenstiev) vyznačujúcich sa určitými spoločnými ekologickými charakteristikami. Diagnostické druhy sú často korelované s určitými ekologickými a geografickými charakteristikami spoločenstiev. Vegetačné jednotky sú väčšinou charakterizované skupinou diagnostických taxónov, vykazujúcich vzájomnú ce-

nologickú koreláciu – spoločný, v prírode sa opakujúci výskyt. Čím početnejšia je skupina diagnostických taxónov, tým výraznejšie je daná jednotka charakterizovaná (MORAVEC 1994b). V niektorých prípadoch majú skupiny diagnostických taxónov iba regionálnu platnosť, v iných územiach (napr. horských celkoch s rozdielou flórogenézou) sa rovnaké druhy môžu vyskytovať v odlišných druhových kombináciách.

Koncepcia diagnostických taxónov sa od svojho vzniku spája s koncepciou fidelity – viazanosťou výskytu resp. dominancie určitých druhov na určité vegetačné jednotky. Prvé prístupy k stanoveniu fidelity jednotlivých druhov boli intuitívne (SZAFAŘ & PAWŁOWSKI 1927), neskôr – s rozvojom výkonnejších počítačov a softvéru na analýzu vegetačných dát, boli nahradené sofistikovanejšími štatistickými metódami a analýzami (cf. GOODAL 1953; JUHÁSZ-NAGY 1964; VAN DER MAAREL et al. 1978; DUFRENE & LEGENDRE 1997; BOTTA-DUKÁT & BORHIDI 1999; BRUELHEIDE 1995, 2000; CHYTRÝ & TICHÝ 2003; CHYTRÝ et al. 2002, 2006).

Počiatocné lokálne štúdie zaoberajúce sa viazanosťou jednotlivých taxónov na určité fytocenózy boli postupom času vyštriedané prehľadmi spoločenstiev rozsiahlejších územných celkov. V rámci bývalého Československa publikovali prvé prehľady všetkých vegetačných typov KLIKA & NOVÁK (1941), KLIKA & HADAČ (1944) a KLIKA (1948, 1955). Spolu s predloženým hierarchickým systémom autori uviedli diagnostické druhy pre triedy, rady a zväzy, pričom nerozlišovali charakteristické a diferenciálne druhy. O niekoľko rokov neskôr HOLUB et al. (1967) uviedli vo svojom prehľade vyšších vegetačných jednotiek Československa skupiny indikačných druhov pre jednotlivé zväzy a podzväzy, ktoré zahŕňali ako druhy charakteristické, tak aj diferenciálne a druhy vyskytujúce sa s vyššou stálosťou. Ako uviedli CHYTRÝ & TICHÝ (2003), všetky tieto publikované zoznamy syntaxónov a ich diagnostických druhov sa vyznačovali veľkou subjektivitou pri výbere konkrétnych diagnostických taxónov a nemožnosťou exaktne rozlísiť taxóny s vysokou frekvenciou, ale nízkou diagnostickou hodnotou.

Boli to práve kolegovia z Masarykovej univerzity v Brne, ktorí nás svojou publikáciou o diagnostických druhoch Českej republiky (CHYTRÝ & TICHÝ 2003) inšpirovali k napísaniu tejto práce. Analyzovali sme dátu zo Slovenskej národnej vegetačnej databázy – SNVD (www.ibot.sav.sk/cdf; cf. VALACHOVIČ 1996, 1999; HEGEDÜŠOVÁ 2007; ŠIBÍKOVÁ et al. 2009), uložené v databázovom programe TURBOVEG (HENNEKENS 1995; HENNEKENS & SCHAMINÉE 2001) rovnakými metódami a predostierame verejnosti štatistickú analýzu recentne dostupných fytocenologických dát z územia Slovenska.

Hlavné ciele predkladanej práce sú: **a)** poukázať na viazanosť jednotlivých taxónov vyskytujúcich sa na území Slovenska k vyšším syntaxónom (zväzom, triedam) pomocou štatistického výpočtu fidelity (cf. CHYTRÝ et al. 2002); **b)** vyhodnotiť kvalitu vymedzenia jednotlivých vyšších syntaxónov tu prezentovaného fytocenologického systému (ktorý je v súčasnosti používaný v SNVD) a zároveň poukázať na jeho prednosti a slabiny.

Prehľad vychádza z analýzy 49 459 fytocenologických zápisov uložených v SNVD dostupných v júni 2007. Záписy boli získané metódami zürišsko-montpellierskej školy (BRAUN-BLANQUET 1964; WESTHOFF & VAN DEN MAAREL 1978), často s použitím modifikovanej 9-člennej Braun-Blanquetovej škály (BARKMAN et al. 1964). Pre analýzu boli dátá exportované do programu JUICE 6.4.6 (TICHÝ 2002). Použité boli iba tie záписy, ktorých zaradenie do fytocenologického systému bolo identifikované aspoň na úrovni zväzu.

V ďalšom kroku sme vyradili záписy, ktoré boli zaznamenané na plochách extrémnych veľkostí (záписy $< 50 \text{ m}^2$ alebo $> 1\,000 \text{ m}^2$ pre lesné fytocenózy; $< 10 \text{ m}^2$ alebo $> 200 \text{ m}^2$

pre kroviny a zápisu < 2 m² alebo > 100 m² pre bylinnú vegetáciu, s výnimkou tried *Salicetea herbaceae* a *Sedo-Scleranthetea*, kde bola znížená spodná hranica plochy zápisu na 1 m²).

Kedže rôzny pôvod dát v rozsiahlych fytocenologických databázach môže významne ovplyvniť výsledky ich spracovania, KNOLLOVÁ et al. (2005) navrhli niekoľko strategických postupov stratifikovaného výberu dát, ktoré môžu zvýšiť reprezentatívnosť analyzovaného súboru dát. Napriek tomu, že napríklad geografická stratifikácia je v súčasnosti často používaná pri podobných štúdiách (cf. CHYTRÝ & TICHÝ 2003, CHYTRÝ et al. 2007), rozhodli sme sa analyzovať naše dátu bez stratifikácie, nakoľko chyba vzniknutá stratou veľkého množstva zápisov pri stratifikácii predovšetkým pri vzácnych spoločenstvách s malým areálom výskytu (napr. spoločenstvá tried *Erico-Pinetea*, *Carici rupestris-Kobresietea*, *Salicetea herbacea*), resp. vylúčením zápisov s nepresne identifikovanými geografickými koordinátami, sa nám javila byť väčšia, ako možné skreslenie frekvencie výskytu druhov v jednotlivých jednotkách vzniknuté v dôsledku nadmerného snímkowania niektorých lokalít.

Taxóny determinované len do úrovne rodu boli vylúčené z analyzovanej matice a niektoré taxóny, vrátane poddruhov a variet, boli zahrnuté do vyšších resp. širšie chápanych taxónov (pozri zoznam str. 12).

Pre charakteristiku vyšších syntaxónov sme použili neutrálnejšie termíny diagnostická skupina taxónov resp. indikačná druhotná skupina (cf. MORAVEC 1994b), a nie taxóny charakteristické a diferenciálne, ako bolo doteraz v slovenských vegetačných prehľadoch zaužívané (cf. VALACHOVIČ et al. 1995, 2001; JAROLÍMEK et al. 1997; KLEMENT et al. 2007). V rámci nich sme rozlíšili taxóny diagnostické, konštantné a dominantné. Matematicky definované diagnostické taxóny, vymedzené na základe teórie fidelity (BRUELHEIDE 1995, CHYTRÝ et al. 2002, CHYTRÝ & TICHÝ 2003, CHYTRÝ 2007) s použitím konzistentných formalizovaných kritérií, určujú striktnejšie pravidlá pri stanovení vernosti jednotlivých druhov. Fidelita vyjadruje diagnostickú hodnotu druhu pre danú jednotku (v našom prípade zväz alebo triedu). Druhy s vysokou hodnotou fidelity (resp. vernosti alebo viazanosti) môžu byť považované za diagnostické (charakteristické alebo diferenciálne). Pre stanovenie fidelity bol použitý koeficient phi (CHYTRÝ et al. 2002), ktorý predstavuje mieru štatistickej väzby medzi výskytom druhov a zápisov v jednotlivých jednotkách (CHYTRÝ 2007). Kedže výpočet fidelity pre jednotlivé skupiny zápisov závisí od pomeru počtu zápisov patriacich do daného syntaxónu k celkovému počtu zápisov a súčasne je každá jednotka zastúpená iným počtom zápisov (CHYTRÝ et al. 2002), relatívny počet zápisov každej jednotky bol virtuálne štandardizovaný tak, že cielová skupina zápisov bola rovnako veľká ako ostatné skupiny zápisov v rámci analyzovaného súboru dát (CHYTRÝ et al. 2006, TICHÝ & CHYTRÝ 2006). Počet zápisov v jednotlivých zväzoch bol štandardizovaný na 1/175 celkového počtu všetkých zápisov v dátovom súbore, v triedach bol počet zápisov štandardizovaný na veľkosť 1/47 z počtu všetkých zápisov v dátovom súbore. Použitie tejto metódy zvyšuje relatívnu homogenitu malých skupín (jednotiek s menším počtom zápisov). Výsledkom je vyšší počet diagnostických taxónov s vyššou fidelitou v malých skupinách. Malé skupiny môžu byť v dôsledku toho nadhodnotené. Aby sme do určitej miery znížili tento jav a zredukovali vplyv náhodne sa vyskytujúcich taxónov v súbore dát, ktoré pri výpočte fidelity mohli dosahovať vysoké hodnoty pre niektoré skupiny zápisov, použili sme Fisherov exaktný test (CHYTRÝ et al. 2002, 2006; CHYTRÝ 2007), pričom za signifikantnú hodnotu sme považovali $P < 0,001$.

Druhy, ktorých koncentrácia výskytu sa nelíšila od koncentrácie pri náhodnom výskytu na uvedenej hladine významnosti neboli zahrnuté medzi diagnostické taxóny. Napriek použitiu tejto metódy, niektoré jednotky s malým počtom zápisov sa javili aj nadľahko ako viac-menej nadhodnotené. Túto skutočnosť je potrebné bráť do úvahy pri interpretácii predkladaných výsledkov. Naopak, ak by sme analyzovali dátá bez následnej virtuálnej štandardizácie na rovnakú veľkosť všetkých skupín, ako to urobili CHYTRÝ & TICHÝ (2003) vo svojej pionierskej štúdii, nastal by opačný efekt – zväzy resp. triedy s malým počtom zápisov by boli podhodnotené a vypočítané hodnoty fidelity pre ne by mohli byť nespoľahlivé v dôsledku vplyvu náhodného efektu. Po zvážení a porovnaní viacerých výsledkov sme preto použili novšiu metódu (TICHÝ & CHYTRÝ 2006) s tým, že treba mať na zreteli, že hodnoty fidelity niektorých druhov v jednotkách zastúpených malým počtom zápisov (často ide o prirodzené vzácné spoločenstvá) môžu byť do určitej miery nadhodnotené.

Za **diagnostické taxóny** pokladáme tie, ktorých hodnota fidelity v jednotlivých syntaxónoch (zväzoch alebo triedach) je väčšia ako 24 ($\Phi > 0,24$). Táto hodnota bola stanovená subjektívne na základe posúdenia výsledkov predchádzajúcich analýz, pričom sme prihliadali na to, aby výsledné počty diagnostických druhov neboli vo všeobecnosti ani príliš vysoké, ani príliš nízke. **Konštantné taxóny** sú vymedzené frekvenciou výskytu v danej jednotke vyššou než 25 % pre triedy a vyššou než 40 % pre zväzy. Za **dominantné taxóny** považujeme tie, ktorých pokryvnosť je vyššia než 50 % v aspoň 3 % zápisov daného syntaxónu. Tako definované diagnostické, konštantné a dominantné taxóny uvádzame v appendixe 2 a 3.

Štatisticky definované diagnostické taxóny umožnili kvantifikovať kvalitu vymedzenia jednotlivých syntaxónov (zväzov a tried), ktoré tu prezentujeme v appendixe 1 a v kapitole 2. Pre tento účel boli použité, podobne ako v práci CHYTRÝ & TICHÝ (2003), kritériá označené ako vyhranenosť (sharpness) a jedinečnosť (uniqueness). **Vyhranenosť** (Tab. 2 a 4) je určená indexom S a vyjadruje počet a/alebo kvalitu diagnostických druhov v danej vegetačnej jednotke v pomere k priemernej druhovej bohatosti porastov tejto jednotky (CHYTRÝ & TICHÝ 2003). Vegetačná jednotka je vyhranená, ak väčšina v nej zastúpených druhov je viazaná len na ňu a chýba v ostatných vegetačných jednotkách. Vysoké hodnoty vyhranenosť dosahujú tie jednotky, ktoré majú veľa diagnostických taxónov s vysokou fidelitou. Nižšie, ale stále vysoké hodnoty dosahujú jednotky s niekoľkými diagnostickými druhmi s vysokou fidelitou alebo veľkým počtom diagnostických druhov s relatívne nízkou fidelitou (CHYTRÝ & TICHÝ 2003). Na základe analýzy dát v SNVD môžeme považovať za najviac vyhranené vzácné sa vyskytujúce spoločenstvá na extrémnych stanovištiach, akými sú druhovo chudobné halofytne spoločenstvá na brehoch brakkických vód triedy *Thero-Suaedetea* a spoločenstvá na viatych pieskoch triedy *Festucetea vaginatae*, spolu s druhovo chudobnými pionierskymi vodnými spoločenstvami tried *Charetea fragilis*, *Potametea* a *Lemnetea*. K dobre vyhraneným triedam s vyššími hodnotami indexu S patria aj reliktné porasty najextrémnejších stanovíšť našich najvyšších hôr s množstvom arkticko-alpínskych taxónov (*Carici rupestris-Kobresietea*) a reliktné borovicové porasty vápencových skalných stien a kaňonov (*Erico-Pinetea*). Naopak, k najmenej vyhraneným patria vysokobylinné a nitrofilné spoločenstvá tried *Mulgedio-Aconitetea* a *Galio-Urticetea*, pravdepodobne kvôli zdieľaniu viacerých taxónov so širšou ekologickou valenciou a čiastočne tiež preto, že z nich časť potenciálne diagnostických taxónov „odčerpali“ floristicky podobné, ale oveľa užšie vymedzené triedy (napr. *Betulo*

carpaticae-Alnetea viridis vs. *Mulgedio-Aconitetea*). Zo zväzov sú najviac vyhranené *Cypero-Spergularion salinae*, *Halo-Trichophorion pumili* a *Puccinellion limosae* z triedy *Festuco-Puccinellietea*, spolu so zväzmi *Littorelion uniflorae* (*Isoeto-Littorelletea*) a *Radiolion linoidis* (*Isoeto-Nanojuncetea*), pravdepodobne v dôsledku ich úzkej ekologickej špecializácie a druhovej chudobnosti jednotlivých porastov (pozri Tab. 4). Viaceré najviac vyhranené zväzy sú zároveň súčasťou najviac vyhranených tried (*Thero-Camphorosmion* – *Thero-Suaedetea*, *Oxytropido-Elynon* – *Carici rupestris-Kobresietea bellardii* a *Charion fragilis* – *Charetea fragilis*).

Jedinečnosť (Tab. 2 a 4) vyjadruje mieru podobnosti jednotiek rovnakého rangu. Syntaxón považujeme za jedinečný, ak žiadny z jeho diagnostických druhov nie je súčasne diagnostickým druhom pre iné vegetačné jednotky. Jedinečnosť jednotky klesá, ak zdieľa niektoré diagnostické druhy s inými jednotkami (CHYTRÝ & TICHÝ 2003). Pri výpočte jedinečnosti bola najskôr vypočítaná asymetrická miera podobnosti medzi dvoma vegetačnými jednotkami (index T). Po vypočítaní indexu T pre všetky dvojice tried a zväzov a ich následnej sumarizácii bol pre každú jednotku vypočítaný index U, ktorý je mierou jedinečnosti a dosahuje nízke hodnoty v tých vegetačných jednotkách, ktorých diagnostické druhy sú prevažne zdieľané s inými syntaxónmi (CHYTRÝ & TICHÝ 2003; TICHÝ & HOLT 2006). Najvyššie hodnoty indexu U dosahujú zriedkavo sa vyskytujúce syntaxóny zastúpené menším počtom zápisov spolu s druhovo chudobnejšími syntaxónmi ekologicky extrémnych stanovišť, pričom niektoré syntaxóny splňajú obidve kritériá Medzi najmenej jedinečné triedy (s najnižšími hodnotami indexu U) môžeme zaradiť jednotky viazané prevažne na subalpinsky stupeň – *Mulgedio-Aconitetea*, *Loiseleurio-Vaccinietea* a *Roso pendulinae-Pinetea mugo*. Obsahujú početné taxóny dosahujúce kladné hodnoty fidelity vo viacerých syntaxónoch. Možno práve nízka frekvencia až absencia užie špecializovaných taxónov, viazanych na túto prechodnú zónu v oblasti hornej hranice lesa, vysvetľuje vysoký počet diagnostických druhov vyskytujúcich sa vo viacerých jednotkách.

V tabuľkách 3 a 5 sú uvedené dvojice tried a zväzov zoradené na základe klesajúcej hodnoty indexu T, ktoré predstavujú najpodobnejšie jednotky v rámci analyzovaného súboru dát. Vo väčšine prípadov ide o floristickú podobnosť medzi štruktúrne odlišnými vegetačnými typmi (napr. *Mulgedio-Aconitetea* a *Betulo carpaticae-Alnetea viridis*, *Loiseleurio-Vaccinietea* a *Caricetea curvulae*, *Elyno-Seslerietea* a *Erico-Pinetea*, *Astro alpini-Seslerion calcariae* a *Pulsatillo slavicae-Pinion*, *Juncion trifidi* a *Loiseleurio-Vaccinion*, *Calamagrostion arundinaceae* a *Salicion silesiacae*, *Calamagrostion variae* a *Pulsatillo slavicae-Pinion*) prípadne sukcesne nadvážujúcimi typmi vegetácie (*Thlaspietea rotundifolii* a *Carici rupestris-Kobresietea bellardii*, *Asplenietea trichomanis* a *Elyno-Seslerietea*, *Potentillion caulescentis* a *Astro alpini-Seslerion calcariae*). Ako podobné sa javili tiež triedy, v ktorých boli zoradené zápisu získané na veľkostne rozdielnych plochách – *Sedo-Scleranthetea* a *Festuco-Brometea*. CHYTRÝ & OTÝPKOVÁ (2003) poukázali na to, že v niektorých situáciach snímkovanie na malých alebo veľkých plochách v tých istých porastoch môže viesť k pričleneniu získaných fytocenologických zápisov k rôznym syntaxónom. Preto je potrebné definovať vegetačné a stanovištné typy s ohľadom na ich závislosť od veľkosti plôch fytocenologických zápisov. Rovnako aj podobnosť medzi triedami *Elyno-Seslerietea* a *Erico-Pinetea* môže byť do určitej miery interpretovaná ako dôsledok rôznych veľkostí plôch analyzovaných fytocenologických zápisov. Zápisu z tried *Sedo-Scleranthetea* a *Elyno-Seslerietea* sú zvyčajne zapisované na menších

plochách než zápisy z tried, s ktorými vytvárali najpodobnejšie páry. V niektorých prípadoch sú floristicky veľmi podobné aj syntaxóny s podobnou štruktúrou a podobnými stanovištnými nárokmi (napr. *Koelerio-Corynephoretea* a *Festucetea vaginatae*, *Quercetea robori-petraeae* a *Pulsatillo-Pinetea*, *Alopecurion pratensis* a *Cnidion venosi*, *Genisto germanicae-Quercion* a *Quercion petraeae*, *Athyrio alpestris-Piceion* a *Chrysanthemo rotundifolii-Piceion*, *Piceion excelsae* a *Abietion albae*). Ako uviedli CHYTRÝ & TICHÝ (2003), v takýchto prípadoch je možné uvažovať o ich zlúčení do jednej vegetačnej jednotky. Vytvorenie najpodobnejších dvojíc zväzmi z rovnakej triedy svedčí o správnosti ich zaradenia (napr. *Vaccinion myrtilli* a *Loiseleurio-Vaccinion*, *Festucion versicoloris* a *Oxytropido-Elynon*, *Sphagnion medi* a *Oxycocco-Empetrium hermaphroditii*).

Predložená štúdia predstavuje štatistickú revíziu dát uložených v SNVD. Pomocou štatisticky determinovaného koeficientu fidelity bola stanovená väzba určitých diagnosticky významných taxónov cievnatých rastlín, machorastov a lišajníkov na vyššie syntaxóny – zväzy a triedy, vyskytujúce sa na Slovensku. Okrem diagnostických taxónov boli stanovené aj druhy konštantne sa vyskytujúce v jednotlivých vyšších syntaxónoch a druhy dominantné.

Zhodnotenie vegetačných jednotiek pomocou kritérií vyhranenosť a jedinečnosť umožnilo odlišenie lepšie a horšie vymedzených zväzov a tried tu prezentovaného fytocenologického systému a určenie problematicky vymedziteľných jednotiek pomocou štatisticky definovaných pravidiel. Pri niektorých zväzoch a triedach s nízkymi hodnotami vyhranenosť a jedinečnosť by mohla byť zvážená revízia ich vymedzenia a postavenia v syntaxonomickom systéme.

Napriek určitým problémom, ktoré môžu ovplyvniť celkový výsledok analýzy veľkého súboru dát (uprednostňovanie zberu dát z určitých typov vegetácie a z určitých regiónov, nízky počet zápisov z niektorých jednotiek, napr. z prirodzene vzácnych spoločenstiev, rôznorodé taxonomickej koncepcie a ľ.), považujeme získané výsledky za užitočné z hľadiska celkového pohľadu na kvalitu a štruktúru dát uložených v SNVD a na kvalitu a použiteľnosť prezentovaného fytocenologického systému.

Veríme, že predkladaná práca pomôže fytocenológom pri generovaní syntaxonomických hypotéz a pri následných overovacích štúdiach a zároveň poslúži ako vhodná príručka a porovnávací etalón pre ostatných botanikov, zoologov, ekológov, pedagógov a študentov na prírodovedne zameraných univerzitách a v ochranárskej a lesníckej praxi.

Appendix 1

A synopsis of alliances and classes analysed in this study

The units are arranged by Turboveg Code (TV CODE) for easy determination of individual syntaxa in the Appendices 2 and 3.

TV CODE	SYNTAXON	ABBREVIATION
01	<i>Alnetea glutinosae</i>	AG
01AA	<i>Salicion cinereae</i>	Sal cin
01BA	<i>Alnion glutinosae</i>	Aln glu
02	<i>Artemisieta vulgaris</i>	AV

Appendix 2

A list of classes and alliances with enumeration of statistically determined diagnostic, constant and dominant species

The codes of classes and alliances are identical with those in the list of syntaxa in SNVD and with codes in the Appendix 1. The syntaxon name is followed by short characteristics of the vegetation unit and the number of processed relevés. Number of diagnostic, constant and dominant taxa, included into each category of diagnostically important taxa is shown in brackets. If a taxon belongs to more than one category within the particular syntaxon, it is followed by a reference to another category (Dg – diagnostic taxa, C – constant taxa, Dm – dominant taxa). Diagnostic taxa are ordered by decreasing value of Phi coefficient ($\Phi > 0.24$) multiplied by 100 to display taxa with the best diagnostic capacity first. Constant taxa include taxa with percentage frequency of occurrence more than 25 % for classes and more than 40 % for alliances. They are in descending order. Dominant taxa comprise taxa with abundance higher than 50 % at least in 3 % of relevés. They are in descending order, so the most frequent dominants are listed first. The most right column refers to the classes and alliances, where the same taxon has also a status either diagnostic, constant or dominant taxon.

For correct interpretation of results, it is important to remember, that small groups (vegetation units with small number of relevés) are usually more homogeneous than bigger ones and they have more diagnostic taxa with higher fidelity. These units are more or less overestimated in consequence of using standardization of analysed dataset to the equal relevé size of all groups.

Class 01 *Alnetea glutinosae*

Appendix 3

Alphabetical list of diagnostic, constant and dominant species of classes and alliances

The taxon name is followed by number of occurrences in the data set (in brackets). Status of the taxon (Dg – diagnostic, C – constant, Dm – dominant) in the relevant vegetation units is depicted by abbreviations of classes (capital letters) and alliances (small letters) in harmony with Appendix 1 and Tables 2 and 4, as well.

2 A list of vegetation units of Slovakia

I. JAROLÍMEK, J. ŠIBÍK, K. HEGEDÜŠOVÁ, M. JANIŠOVÁ, J. KLIMENT,
 P. KUČERA, J. MÁJEKOVÁ, D. MICHÁLKOVÁ, J. SADLOŇOVÁ,
 I. ŠIBÍKOVÁ, I. ŠKODOVÁ, J. UHLÍŘOVÁ, K. UJHÁZY, M. UJHÁZYOVÁ,
 M. VALACHOVIČ & M. ZALIBEROVÁ

A synopsis of syntaxa occurring in Slovakia with most frequent synonyms, homonyms, and pseudonyms, which are supplemented in brackets below the name of syntaxon. This list of vegetation units (syntaxa) was compiled for purposes of statistical analyses of the SNVD in June 2007 according to the list of syntaxa used in that time in SNVD. Newer syntaxonomical concepts were not included in order to keep consistence between originally analysed syntaxa and those presented in this work. Latest syntaxonomical concepts of some syntaxa are mentioned in footnotes.

Explanations: # – syntaxon not analysed in this study; ? – syntaxon potentially occurring in Slovakia, but represented by no relevé in current SNVD; § – name needs revision; !!! – syntaxon needs revision.

The list of syntaxa follows this scheme:

	Chapter 2	(App. 2)
2.1 Aquatic, shoreline and swamp vegetation		
<i>LEMNETEA</i>	p. 297	(98)
<i>CHARETEA FRAGILIS</i>	p. 297	(205)
<i>POTAMETEA</i>	p. 297	(136)
<i>ISOËTO-LITTORELLETEA</i>	p. 298	(100)
<i>ISOËTO-NANOJUNCETEA</i>	p. 298	(92)
<i>PHRAGMITO-MAGNOCARICETEA</i>	p. 299	(132)
2.2 Springs, fens and bogs		
<i>MONTIO-CARDAMINETEA</i>	p. 300	(120)
<i>SCHEUCHZERIO-CARICETEA FUSCAE</i>	p. 301	(168)
<i>OXYCOCCO-SPHAGNETEA</i>	p. 302	(203)
2.3 Vegetation of rock fissures, screes and primitive shallow rocky soils		
<i>ASPLENIETEA TRICHOMANIS</i>	p. 302	(58)
<i>THLASPIETEA ROTUNDIFOLII</i>	p. 303	(186)
<i>SEDO-SCLERANTHETEA</i>	p. 303	(184)

2.4 High-mountain swards, heaths, tall-herb and snow-bed vegetation

<i>MULGEDIO-ACONITETEA</i>	p. 304	(124)
<i>ELYNO-SESLERIETEA</i>	p. 305	(63)
<i>CARICI RUPESTRIS-KOBRESIETEA BELLARDII</i>	p. 306	(206)
<i>CARICETEA CURVULAE</i>	p. 307	(94)
<i>LOISELEURIO-VACCINIETEA</i>	p. 307	(219)
<i> SALICETEA HERBACEAE</i>	p. 308	(160)

2.5 Grasslands, meadows, pastures, subhalophilous and fringe vegetation

<i>KOELERIO-CORYNEPHORETEA</i>	p. 308	(97)
<i>FESTUCETEA VAGINATAE</i>	p. 308	(77)
<i>FESTUCO-PUCCINELLIETEA</i>	p. 309	(87)
<i> THERO-SALICORNIETEA</i>	p. 309	(186)
<i>FESTUCO-BROMETEA</i>	p. 309	(78)
<i>TRIFOLIO-GERANIETEA SANGUINEI</i>	p. 311	(190)
<i>MOLINIO-ARRHENATHERETEA</i>	p. 311	(102)
<i>NARDETEA STRICTAE</i>	p. 315	(228)
<i>CALLUNO-ULICETEA</i>	p. 315	(232)

2.6 Shrub vegetation

<i>FRANGULETEA</i>	p. 316	(238)
<i>RHAMNO-PRUNETEA</i>	p. 316	(154)
<i>BETULO CARPATICAE-ALNETEA VIRIDIS</i>	p. 317	(222)
<i>ROSO PENDULINAE-PINETEA MUGO</i>	p. 317	(217)

2.7 Forests

<i>VACCINIO ULIGINOSI-PINETEA SYLVESTRIS</i>	p. 317	(235)
<i>MOLINIO-BETULETEA PUBESCENTIS</i>	p. 318	(117)
<i>ALNETEA GLUTINOSAE</i>	p. 318	(51)
<i>SALICETEA PURPUREAE</i>	p. 318	(164)
<i>QUERCETEA ROBORI-PETRAEAE</i>	p. 318	(142)
<i>QUERCO-FAGETEA</i>	p. 319	(144)
<i>PULSATILLO-PINETEA</i>	p. 321	(138)
<i>ERICO-PINETEA</i>	p. 321	(71)
<i>VACCINIO-PICEETEA</i>	p. 321	(193)
<i>ROBINIETEA</i>	p. 322	(158)

2.8 Synanthropic vegetation

<i>EPILOBIETEA ANGUSTIFOLII</i>	p. 323	(68)
<i>GALIO-URTICETEA</i>	p. 323	(212)
<i>ARTEMISIETEA VULGARIS</i>	p. 324	(54)
<i>BIDENTETEA TRIPARTITAE</i>	p. 326	(61)
<i>POLYGONO ARENASTRI-POETEA ANNUAE</i>	p. 326	(134)
<i>STELLARIETEA MEDIAE</i>	p. 327	(176)

2.1 Aquatic, shoreline and swamp vegetation

ACADEMY
OF SCIENCES

Diagnostic, constant and dominant species of the higher vegetation units of Slovakia. Ivan Jarolímek, Jozef Sibík

This study represents the statistical revision of phytosociological data stored in the Slovak national vegetation database SNVD. The affinities of vascular plants, bryophytes and lichens occurring in Slovakia to the major syntaxa (alliances and classes) are calculated using a statistically defined coefficient of fidelity. In addition, constant and dominant taxa of particular syntaxa are identified. A revised list of syntaxa (vegetation units) of Slovakia is also presented.

The evaluation of vegetation units by sharpness and uniqueness criteria allows us to identify well delimited alliances and classes or to point out those, for which delimitation is problematic and which are more difficult to define by statistical principles. The syntaxonomical revision and delimitation of some units with low values of sharpness and uniqueness should be considered in future.

The presented results are important not only for scientists (botanists, zoologists, and ecologists), but also for nature conservation institutions. They represent a valuable and essential source of floristic data on the occurrence of vascular and non-vascular plants in plant communities with specific environmental characteristics.

Predložená štúdia predstavuje štatistickú revíziu dát uložených v slovenskej národnej vegetačnej databáze SNVD. Pomocou štatisticky determinovaného koeficientu fidelity bola stanovená väzba určitých diagnosticky významných taxónov cievnatých rastlín, machorastov a lišajníkov na vyššie syntaxóny zväzy a triedy, vyskytujúce sa na Slovensku. Okrem diagnostických taxónov boli stanovené aj druhy konštantne sa vyskytujúce v jednotlivých vyšších syntaxónoch a druhy dominantné. Súčasťou publikácie je tiež aktuálny zoznam vegetačných jednotiek Slovenska.

Zhodnotenie vegetačných jednotiek pomocou kritérií vyhranenosť a jedinečnosti umožnilo odlišenie lepšie a horšie vymedzených zväzov a tried tu prezentovaného fytocenologického systému a určenie problematicky vymedziteľných jednotiek pomocou štatisticky definovaných pravidiel. Pri niektorých zväzoch a triedach s nízkymi hodnotami vyhranenosťi a jedinečnosti by mohla byť zväžená revízia ich vymedzenia a postavenia v syntaxonomickom systéme.

Veríme, že predkladaná práca pomôže fytocenológom pri generovaní syntaxonomických hypotéz a pri následných overovacích štúdiách a zároveň poslúži ako vhodná príručka a porovnávací etalón pre ostatných botanikov, zoologov, ekológov, pedagógov a študentov na prírodrovedne zamieraných univerzitách a v ochranárskej a lesníckej praxi.
